Abstract—The newly introduced gap waveguide technology offers non-contact waveguide configurations so that the good electrical contact between different metallic layers can be avoided. Thereby, the gap waveguide structures are relatively simple to manufacture, especially at millimeter and sub-millimeter wave frequencies. This work systematically presents a high-efficiency corporate-fed slot array antenna based on groove gap waveguide in the millimeter waves. A cavity-backed slot sub-array is firstly designed in a groove gap waveguide cavity. The cavity is fed through a coupling hole from groove gap waveguide distribution network at the bottom layer. The sub-array is numerically optimized in an infinite array environment. Low side lobes are obtained in the both E- and H-planes by diagonal placement of the radiation slot rotating by 45 degrees. Furthermore, the radiation narrow slot pair is adopted so that the good cross polarization is achieved. The fabricated antenna depicts more than 25% bandwidth with input reflection coefficient better than -8 dB and the aperture efficiency higher than 60% with around 25 dBi realized gain between 70 and 90 GHz. The measured cross polarization level is below -27 dB, which satisfies the ETSI standard.

Index Terms—groove gap waveguide, wide band slot array antenna.

I. INTRODUCTION

Recently, the saturation of spectrum at microwave frequencies causes the consideration of higher frequency bands. Especially, the millimeter wave range between 30 GHz and 300 GHz has been paid lots of attentions [1]-[2]. Furthermore, the usage of the millimeter wave frequencies has the advantage of allowing for larger bandwidths, and thereby, achieving higher data transfer rates. In such frequency ranges, traditional hollow waveguide and microstrip lines have met up with difficulties to design antennas and passive components. Indeed, hollow waveguide are normally manufactured in two parts and then joined together. In microwave frequency band, it is still convenient to fabricate hollow waveguide because its geometrical dimensions are large. However, its fabrication becomes a big problem because its dimensions are very small in millimeter waves. Moreover, it suffers from problems of irregular rectangular shape and poor electrical contacts. Diffusion bonding and vacuum welding are probably two manufacture technologies for hollow waveguide in millimeter waves [3]. Nevertheless, its fabrication cost is relatively high. On the other hand, microstrip lines or covered microstrip lines are able to integrate the active components, but still present high dielectric losses in millimeter waves. Thereby, new technologies in millimeter waves are still demanded.

Substrate integrated waveguide (SIW) is a appropriate candidate in millimeter waves. Nevertheless, it exhibits undesired dielectric losses in the substrate at increasing frequencies. As is well known, the loss tangent value of substrate increases versus the frequency. Thereby, the dielectric loss in SIW is unacceptable above 60 GHz so that the antenna efficiency is affected [4]-[5]. In such a situation, there is still need to find new technological solutions for waveguides that have low losses and are cheap to manufacture. The recently introduced gap waveguide technology [6] constitutes a new type of guiding structure that shows lot of potential to overcome the issues of conventional technologies, and become a suitable approach at millimeter wave frequencies. First of all, the gap waveguide shows low loss compared with microstrip, covered microstrip and SIW. Secondly, unlike the conventional manufacture of hollow waveguide, the gap waveguide structure is very flexible to be manufacture. Most importantly, the electrical contact between the building blocks is not needed in this new guiding structure so that expensive fabrication technologies, such as vacuum welding and diffusion bonding, can be avoided in millimeter waves. Until now four different variety of gap technology, ridge gap waveguide, groove gap waveguide, microstrip-gap waveguide, and inverted microstrip-

ridge gap waveguide have been already investigated. In [7]-[9] slot array antennas based on gap waveguide technology have been finished. They are able to achieve characteristics of high-gain and high-efficiency because of low loss property. In [10]-[11] filter and duplexer have been developed. In addition, gap waveguide is also able to be applied for microwave circuits packaging [12].

In this work, we Initially introduce a 45° linearly polarized corporate-feed groove gap waveguide slot array antenna covering 71.5 to 90 GHz. As depicted in Fig. 1, the whole slot array antenna consists of the distribution feeding networks, the backed cavity layer, the middle slot layer and the top radiation slot layer. The feeding part is composed of equally-split H-plane T-junctions and a vertical transition from WR-10 standard hollow waveguide from its back. In order to satisfy the radiation pattern of ETSI standard, the radiation slots in this work have been 45° rotated [13]-[14]. Given the rising of the cross polarization level caused by 45° degree rotation, a narrow-slot pair configuration on the top is designed to suppress the cross-polarization. The proposed antenna has been fabricated by computerized numerical control (CNC) milling machine. The measured reflection coefficient and far-field radiation patterns are discussed in the end.

II. DESIGN OF SUB-ARRAY

The pin dimensions of bed of nails at both distribution networks and backed cavities should be chosen correctly to achieve a parallel plate stopband which covers as much as the operating frequency. As depicted in Fig. 2 (a), the design unit cell of proposed groove gap waveguide is built with PEC, periodic and PEC boundary conditions in x-, y- and z-axis in CST Microwave Studio, respectively. Correspondingly, the dispersion diagram of the structure is shown in Fig. 2(b), which is obtained by utilizing the eigenmode solver in CST.

Microwave Studio. The obtained stopband is from 65 to 115 GHz. The proposed $2 \times 2$ sub-array is illustrated in Fig. 3. The sub-array consists of four layers — the top pair radiation layer, the middle slot layer, the backed cavity layer and the bottom distribution feed networks layer. An air-filled cavity formed by pins, feeds four radiating slots with spacing smaller than 3.1 mm, which is equal to one wavelength on the top layer. A groove gap waveguide excites the cavity via a coupling slot on the bottom layer. There is a small gap between each layers and thereby no electrical contact between the different layers. This is a manufacturing advantage of this technology. The designed sub-array has $6 \times 6 \ mm^2$ dimensions. The sub-array is optimized in the infinite array environment by using CST Microwave Studio where the mutual coupling between sub-arrays are automatically included. The simulated reflection coefficient of the sub-array is illustrated in Fig. 4. The sub-array bandwidth is 29% (71 – 95 GHz) with the VSWR better than 1.7. The directivity versus frequency of an array with the same aperture size is shown in Fig. 5. The blue line in the graph shows the maximum available directivity between 100% and 80% aperture efficiency, which clearly shows that the designed sub-array has high aperture efficiency. In Fig. 6, the E- and H-plane far field patterns of an array with $32 \times 32$ slots over its aperture are illustrated for different frequencies.
GHz, respectively. In the 71—89 GHz band, the gain variation is 25—26.2 dBi. The bandwidth for a gain of more than 25 dBi and the antenna efficiency of more than 60% is greatly improved. The cross polarization is suppressed below -27 dB over the full bandwidth. In [14] the the cross polarization level are very well pressed under -30 dB, but this work has not achieved the outcome. The main reason for the problem is that the assembly of the four layers array antenna always has small geometrical errors, which makes the drop of gain and the rise of the cross-polarization and the reflection coefficient.

IV. CONCLUSION

In this work, we present a 45 degree 8 × 8 cavity-backed slot array antenna based on groove gap waveguide for high-gain 80 GHz. The proposed antenna consists of four layers, i.e. 45 degree radiation slot layer, middle coupling slot layer, backed cavity layer and feeding network layers without need of electrical contact between layers. This presents manufacturing advantages in particular at millimeter wave. The array antenna can be directly connected with standard WR-10 interface. The measured gain is higher than 25 dBi from 71 to 90 GHz, correspondingly the antenna efficiency larger than 60%.

V. ACKNOWLEDGEMENT

The authors would like to thanks Dr. Kuikui Fan at Southeast University in Nanjing for the measurement of the reflection coefficient and Shanghai Academy of Spaceflight Technology for the measurement of the gain and cross polarization level.
