Effects on metal resource use from reusing laptops
- A comparison of impact assessment methods

Hampus André, Maria Ljunggren Söderman and Anders Nordelöf

Introduction
- Case study based on a Swedish IT resale company acquiring used but largely functional laptops from companies and reselling to public sector, private users and companies abroad.
- Circular Economy (CE) measures based on extended use, such as reuse, tend to reduce scarce metal losses in two principal ways compared to conventional alternatives:
  - through extending the use of products that can be reused
  - through collecting products that are deemed non-reusable at inspection and sending them to recycling, thereby increasing collection rates
- Metal resource use/depletion/consumption results are considerably dependent on the choice of life cycle impact assessment (LCIA) method (e.g. Finnveden et al., 2016; Peters & Weil, 2016; Rigamonti et al., 2016; Renbech et al., 2014)
- Hence, fruitful to study the effects of reuse using several complementary LCIA methods

Research question
- How does the application of different LCIA methods for metal resource use influence interpretations of reuse of laptops, as mediated by a resale company?

Methodology
- Comparative life cycle assessment (LCA) between:
  - New laptop alternative: new production (every three years)
  - Second-hand laptop alternative (70 % of laptops collected by reuse company used for additional three years)

Results & Discussions
- Case study based on a Swedish IT resale company acquiring used but largely functional laptops from companies and reselling to public sector, private users and companies abroad.
- Metal resource use/depletion/consumption results are considerably dependent on the choice of life cycle impact assessment (LCIA) method (e.g. Finnveden et al., 2016; Peters & Weil, 2016; Rigamonti et al., 2016; Renbech et al., 2014)
- Hence, fruitful to study the effects of reuse using several complementary LCIA methods

Conclusions
- Major reduction from use extension:
  - about 41% due to doubled lifetime of 70% of sourced laptops
  - Additional reduction from steering flows into recycling depending on LCIA method:
    - especially important according to some LCIA-methods (varying between 1-9% reduction compared to new laptops) which characterise metals that are functionally recycled as important (typically methods using average crustal concentrations) and negligible in others (typically reserve-based methods)
    - The benefits most from reuse are functionally recycled metals (silver, gold, copper, palladium, tin and nickel)
    - The reuse company’s routine of steering flows into recycling decreases their losses in addition to use extension.

- A advisable to use complementary methods to minimise risks of overlooking relevant metal resource use aspects when studying circular economy measures applied to electronic products

Table 1. LCIA methods used, problem perceptions, indicator approach (Stein, 2006; Sonderegger et al., 2017) and type of data used to derive characterisation factors.
