Graphene is a promising material for high frequency electronics applications thanks to its intrinsically high carrier mobility and velocity, and graphene transistors are continuously pushed toward higher operating frequencies [1]. For high frequency low noise amplifiers, it is important to evaluate the noise parameters of the graphene field-effect transistors (GFETs). In this work, we present the noise performance of the GFETs made of chemical vapour deposition (CVD) in the frequency and temperature ranges of 2-18 GHz and -60-25 °C. The noise figure with 50 Ω impedance termination ($F_{50}$) was measured using the cold-source method and then the minimum noise figure ($F_{\text{min}}$) was estimated using the Pospieszalski’s noise model [2, 3]. In Fig. 1 and Fig. 2, the $F_{\text{min}}$ of a GFET with a gate length of 0.5 μm as a function of the frequency ($f$) and drain voltage ($V_d$) at different temperatures are shown. This GFET revealed maximum frequency of oscillation ($f_{\max}$) of 18 and 21 GHz at 25 and -60 °C, respectively. It can be seen from Fig. 1, that the $F_{\text{min}}$ at 8 GHz is approx. 2 dB lower than that of the previously published CVD GFETs and comparable with that of the best published SiC GFETs [4, 5]. The $F_{\text{min}}$ decreases significantly with temperature down to 0.3 dB at 8 GHz, competing with Si CMOS [6]. It can be seen from Fig. 2, that $F_{\text{min}}$ decreases with the $V_d$ and saturates above approx. 1 V, where GFETs operate in the velocity saturation mode [1]. Analysis of the dependences allows for further development of the GFETs for advanced low noise amplifiers.

Fig. 1. $F_{\text{min}}$ versus frequency at different temperatures (-60, -45, -25 and 25 °C), gate voltage of 0.5 V and drain voltage of -1.4 V.

Fig. 2. $F_{\text{min}}$ versus drain voltage at temperature of -60°C for different frequencies (2, 6, 10, 14 and 18 GHz) at gate voltage of 0.5 V.
