ABSTRACT: Microbial arene oxidation of benzoic acid with *Ralstonia eutropha* B9 provides a chiral highly functionalized cyclohexadiene, suitable for further structural diversification. Subjecting this scaffold to a Pd-catalyzed Heck reaction effects a regio- and stereoselective arylation of the cyclohexadiene ring, with 1,3-chirality transfer of stereogenic information installed in the microbial arene oxidation. Quantum chemical calculations explain the selectivity both by a kinetic preference for the observed arylation position and by reversible carbopalladation in competing positions. Further product transformation allowed the formation of a tricyclic ketone possessing four stereogenic centers. This demonstrates the capability of the method to introduce stereochemical complexity from planar nonchiral benzoic acid in just a few steps.
The biocatalytic transformation of arenes into dearomatized *cis*-dihydroxylated species can be achieved using arene dioxygenase enzymes via microbial arene oxidation (MAO).[1] While complete oxidation affords a catechol, the use of mutant strains[2] or recombinant organisms[3] allows isolation of the intermediate chiral diol, enabling conversion of a flat arene into a chiral functionalized scaffold, suitable for further transformations. Many dioxygenase enzymes are known and generally lead to *ortho*/*meta* dihydroxylation with respect to pre-existing functionality.[4] However, benzoate dioxygenase (BZDO), expressed by *R. eutropha* B9,[5] transforms benzoic acid with complementary selectivity, affording *ipso*/*ortho* dihydroxylated product **1** as a single enantiomer (Scheme 1a). Compound **1** has been subjected to various transformations such as oxidations and acetalization[6] and been used for preparing natural products[7] and pharmaceuticals.[8] One diversification approach could involve metal-catalyzed cross-coupling of the diene sp²-carbons.[9] The Mizoroki−Heck reaction[10] allows arylation of an alkene under Pd-catalysis and can potentially lead to chirality transfer from one ring carbon to another. Such chirality transfer has been demonstrated in the synthesis of *C*-glycosides,[11] where the coupling effects a double bond migration and 1,3-chirality transfer (Scheme 1b). However, achieving selectivity with a diene such as **1** could be challenging. Studies of Pd-catalyzed reactions involving substrates obtained via MAO are limited,[6c,12] and to the best of our knowledge, Heck arylation of **1** and its derivatives has not been described. Furthermore, this type of chirality transfer in intermolecular Heck reactions has not been investigated to any great extent outside of glycal arylations. We herein report

**Scheme 1. Arylation of Microbial Arene Oxidation Products**
our findings concerning the conversion of esters and amides **2**, obtained from **1**, into chiral arylated 1,4-dienes such as **3** (Scheme 1c). A quantum chemical study was also conducted to elucidate the origin of the high selectivity.

Results and Discussion. Ester **2a** (Table 1), with an acetal protected *cis*-diol, was chosen as a suitable substrate and was

subjected to Pd-catalyzed arylation with iodobenzene. With a diene such as **2a**, several products can potentially be formed under these conditions. However, we were gratified to see that using iodobenzene, Pd(OAc)$_2$, and AgOAc in acetonitrile resulted in the completely regio- and diastereoselective arylation of **2a** to form diene **3aa** in 60% yield (Table 1, entry 1). Through this reaction, stereochemical information initially present in the diol moiety is transferred to a more distal position.

Other bases and silver sources are less effective (entries 2−4), but the amount of silver salt could be reduced to 1.4 equiv, maintaining the same reactivity (entry 5). However, a palladium loading of 10% and 4 equiv of the aryl iodide were necessary for full conversion and a high degree of product formation. A range of phosphine ligands were subsequently screened (entries 6−9), and P((4-CF$_3$)C$_6$H$_4$)$_3$ (entry 9) was identified as most effective. After reassessing the reaction conditions, the use of P((4-CF$_3$)C$_6$H$_4$)$_3$ allows the palladium and ligand loading to be reduced to 5% and 10%, respectively, while maintaining comparable reactivity (entry 10; see Supporting Information (SI) for full optimization).

With the optimized conditions in hand, we investigated the scope of arylation reagents using ester **2a** (Scheme 2). Aryl iodides with electron-rich or -neutral substituents at the *para* position perform comparably well, providing the arylated products in good yields (compounds **3aa−3ad**). Electron-deficient arenes afford products in somewhat lower yields (**3ae−3af**). Notably, 1-bromo-4-iodobenzene reacts selectively at the Ar−I bond, producing 66% of **3ae**. Different substitution patterns on the aryl ring are also tolerated with 2- or 3-substituted aryl iodides (**3af−3am**). In terms of limitations, certain functional groups are not tolerated on the aryl iodide, including aldehyde, phenol, and amine. Whereas indole can be

coupled to the 7-position (**3am**), other heterocyclic aryl iodides are unsuccessful. Likewise, other aryl halides or pseudohalides do not react under these conditions. A crystal structure of compound **3ah** (Figure 1) verifies this structure unequivocally.

We next investigated the scope of the starting diene. In addition to ester **2a**, amides and secondary esters perform well, affording **3ba−3db** in good yields (Scheme 3). Furthermore, a Weinreb amide, as in **3eb**, could be applied and is potentially useful for postfunctionalization. Substrates **1** and **4−6** were also tested but did not afford arylated products.

We subsequently explored further synthetic transformations of products **3**. Cleavage of the acetal in **3ba** and **3bf**, using CF₃COOH, afforded ketones **7ba** and **7bf** in high yields (Scheme 4, route A). Compound **7bf**, containing a ketone and a proximal ester group, could potentially undergo an

intramolecular Claisen condensation, and this feature was investigated. Treating **7bf** with NaOMe in methanol led to the formation of aromatized fluorenone **8** in 71% yield, following elimination of H₂O. While this demonstrates the applicability of these products as enolates, valuable stereochemical information is lost here. To explore other possibilities, we subjected **3bi**, with two acetal functionalities, to acidic conditions, envisaging that both groups could be deprotected in one step (Scheme 4, route B). A subsequent acid catalyzed aldol reaction could then result in a cyclized product. We were delighted to see that the use of *p*-TsOH in wet acetonitrile led to the formation of tricyclic compound **9**. Remarkably, this product, which contains four stereogenic centers, forms with complete diastereoselectivity. This reaction demonstrates that our method can be utilized to build up significant molecular complexity from a flat achiral starting material, benzoic acid.

In order to explain the high regioselectivity and facial selectivity of the transformation, we have performed a quantum chemical study, relying on Density Functional Theory (DFT) calculations. Our calculations, which were done with Gaussian16,[13] were mostly performed at the B3LYP-D3/def2-TZVP//def2-SVPD level of theory. The Solvent Model Density (SMD) method was used to include implicit consideration of acetonitrile solvation effects.[14] More details of the calculations are given in the Supporting Information. The B3LYP-D3 functional has a reported mean average deviation from CCSD(T)/CSB results of 1.6 and 2.3 kcal/mol for barrier heights and reaction energies, respectively, in a selection of Pd-catalyzed reactions.[15] The method has also previously been used to model Heck reactions.[16]

The formation of **3aa**, without phosphine ligands, was chosen as a model system for our calculations (Table 1, entry 5). Because the experimental reaction was performed with a silver additive in a polar solvent, a fast halide abstraction from palladium was assumed. In other words, all structures were modeled using acetate and acetonitrile ligands.

An extensive screening of migratory insertion transition states and their conformational space was conducted (see SI). Transition state structures (**TS1−TS8**) for the eight possible arylations are shown in Figure 2. For each possibility, the complexes are depicted in their lowest energy ligand conformations. The lowest energy pathway, **TS1** (see SI, Figure S86), leads to C−C bond formation in the C-4 position,
Figure 2. Top: Gibbs energy profile (1M, 298 K, in kcal/mol) for four of the migratory insertion transition states. Single point energies are calculated at the B3LYP-D3/def2-TZVP and M06/def2-TZVP (within parentheses) levels of theory. Bottom: Structures for higher energy migratory insertion transition states. Energies are shown relative to **TS1**.

on the face *anti* to the acetonide moiety. It corresponds well to previously reported Heck-type migratory insertion transition states, with an almost fully formed Pd−C bond along with a developing C−C bond.[17] Our calculations predict that **TS1** is favored by 1.8 kcal/mol over the second lowest, **TS2** (Figure 2). The predominance of **TS1** in determining the reaction outcome agrees well with our experimental results, in which **3aa** is the only observed Heck product. In addition to **TS2**, other transition states near in energy to **TS1** might contribute under our experimental conditions. These are **TS3**, predicted to lie 2.1 kcal/mol higher than **TS1**, as well as **TS4** and **TS5**, higher by 2.3 and 2.4 kcal/mol, respectively.

The insertion products following **TS1**, **TS2**, and **TS3** all correspond to structures with palladium bound to an sp³-carbon. These structures, **IN1**, **IN2**, and **IN3**, are all relatively close in energy, with **IN2** somewhat less stable, possibly due to steric effects from installing the palladium *syn* to the acetonide. Insertion product **IN5** is different and is significantly more stable compared to **IN1-3**. The difference can be explained as a result of the formation of a palladium π-allyl system. The insertion products **IN2** and **IN3** do not have any available β-hydrogens, and therefore both lack obvious forward reaction paths toward a Heck-type product (the same holds true for the insertion product following **TS4**).

One possibility in the absence of β-hydrogens is a reverse carbopalladation. In a Heck-type reaction, the migratory insertion is generally viewed as irreversible;[17b,c,18] there are however known examples of β-carbon elimination when no β-hydrogens are available.[19] We have estimated the backward reaction barriers for migratory insertion products **IN2** and **IN3** to ∼21 kcal/mol and ∼26 kcal/mol, respectively. These barriers imply that such processes are accessible under the experimental conditions. Therefore, if formed, the formation of **IN2** and **IN3** should be reversible, and these should be able to proceed to Heck-product **3aa**. With a backward reaction barrier of ∼33 kcal/mol, the formation of **IN5** is irreversible.

In contrast to **IN2** and **IN3**, intermediate **IN1** possesses a hydrogen in a *syn* orientation with respect to the palladium. As expected, a β-hydride elimination is predicted to follow. The β-hydride elimination forming product **3aa** was computed to have a barrier of 16 kcal/mol (**TS9**). In accordance with the increased stability of the π-allyl system, the barrier for β-hydride elimination in **IN5** (**TS10**) was calculated to be 26 kcal/mol, which should be attainable under the experimental conditions. If formed, **IN5** should proceed to form Heck-product **10** (Figure 2).

Conclusions. We here present a methodology for Pd-catalyzed diastereoselective arylation of dienes derived from

enzymatic *cis*-dihydroxylation of benzoic acid. This approach allows for a chirality transfer from the diol moieties of these microbial arene oxidation products to a more distal position, increasing the chiral pool of molecules available by enzymatic dearomatization. The reaction effects coupling of a range of aryl iodides in moderate to excellent yields and selectivity and provides the opportunity to form tricyclic scaffolds via further transformations. A quantum chemical investigation indicates that there is a kinetic preference for arylation in the observed position. Interestingly, it was also found that reversibility in the other accessible carbopalladations might be kinetically relevant for the high selectivity toward the formed Heck product.
