When is repair environmentally beneficial? The case of high-voltage electric motors

1) Context

One energy-intensive product: high voltage electric motors used in industry (e.g., pumps and compressors in chemical and metal industries)

- 30 tons of steel, copper and plastics,
- In operation for 50 weeks/year in Sweden,
- Output power of 16 MW,

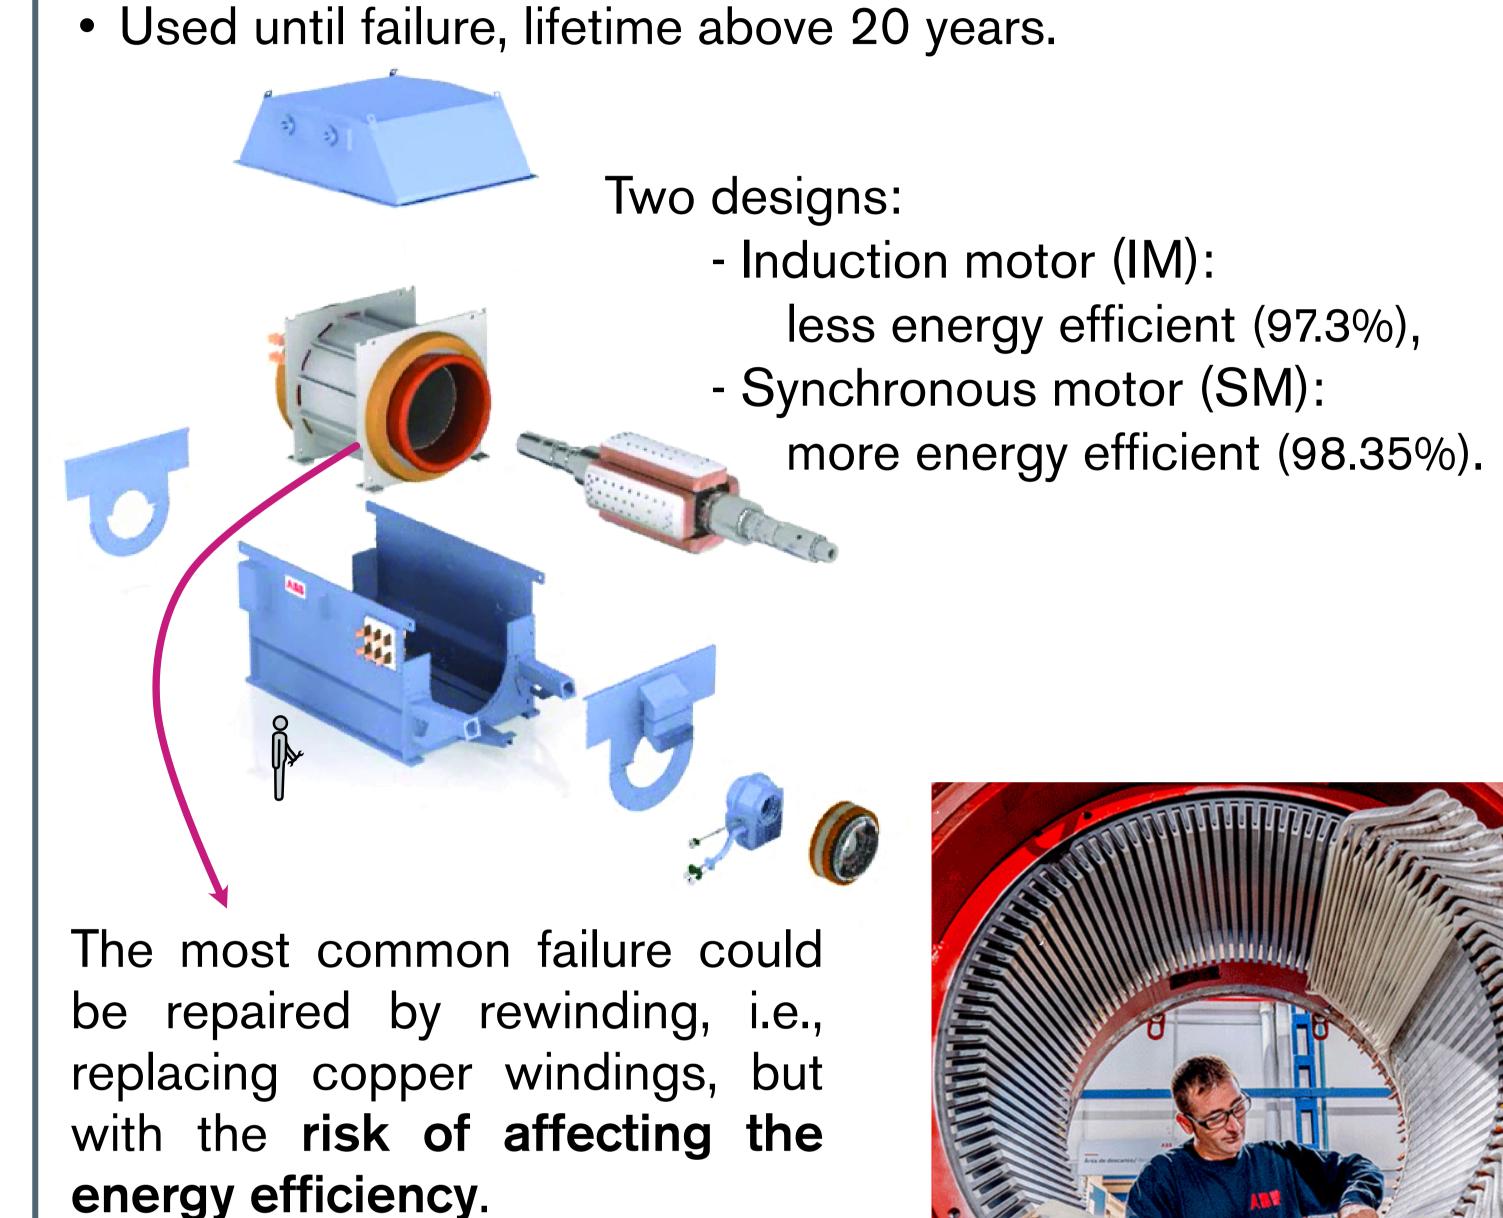

Legend

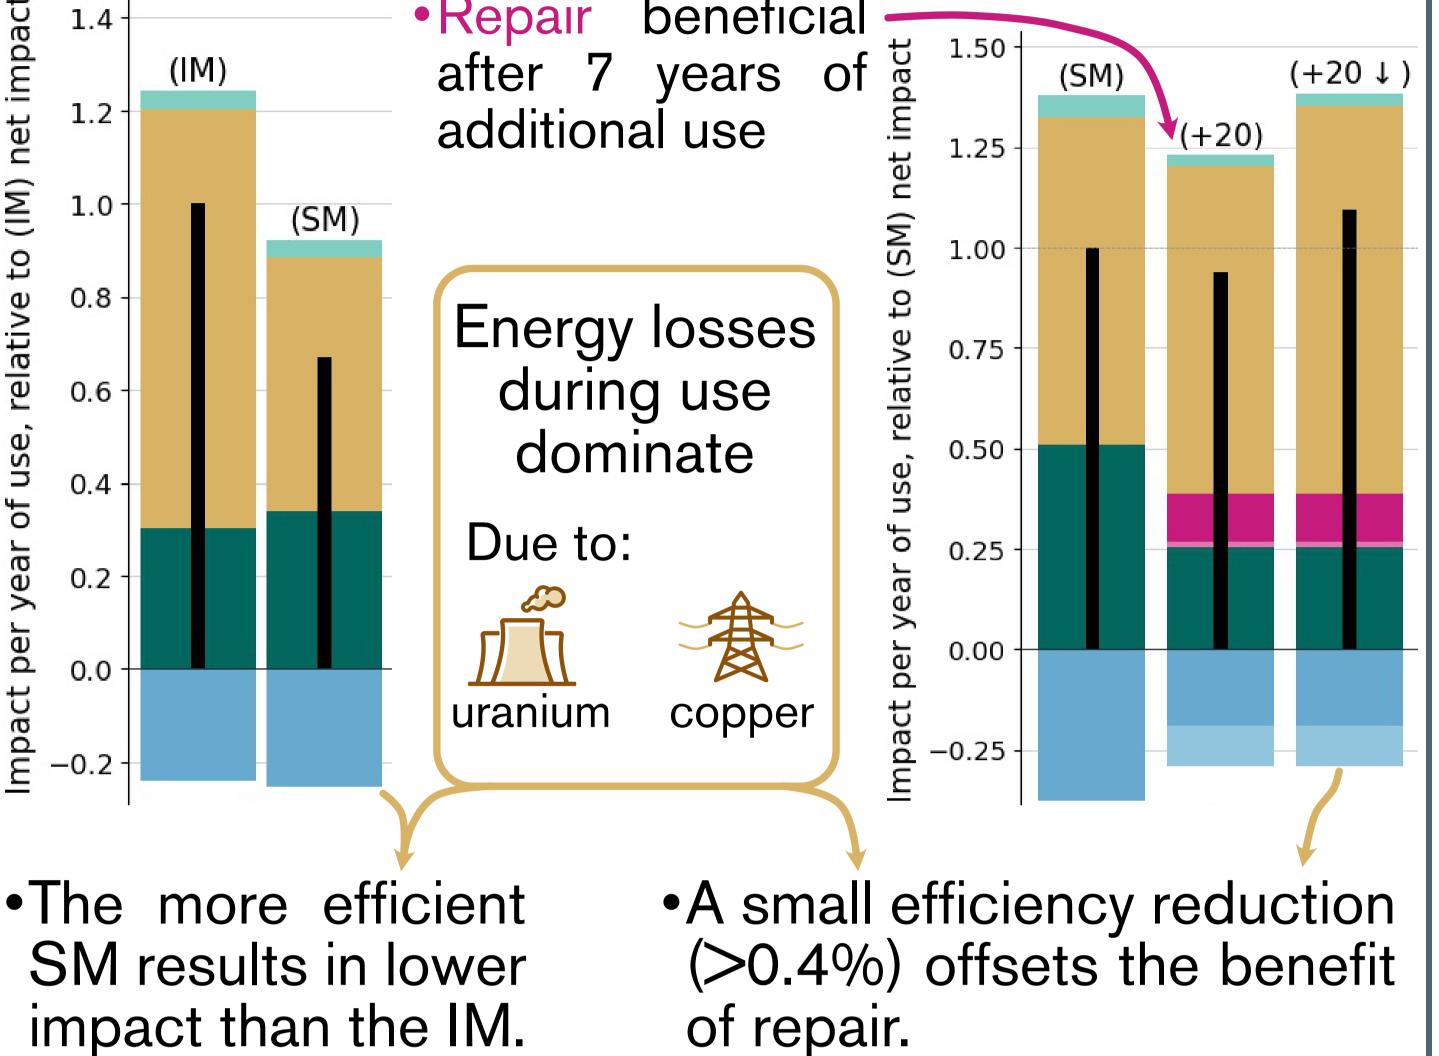

ati

(IM): induction motor, used for 20 years (SM): synchronous motor, used for 20 years Motor recycling **Electricity losses during use Motor production Credits from motor recycling**

(+20): SM repaired and used for 20 additional years $(+20\downarrow)$: (+20) with an efficiency reduction of 0.6%

Rewinding **Old windings recycling Credits from windings recycling**

The impact reduction from SM's better efficiency outweighs its higher impact from extraction and production (more copper in the motor).

2 Results - Global warming

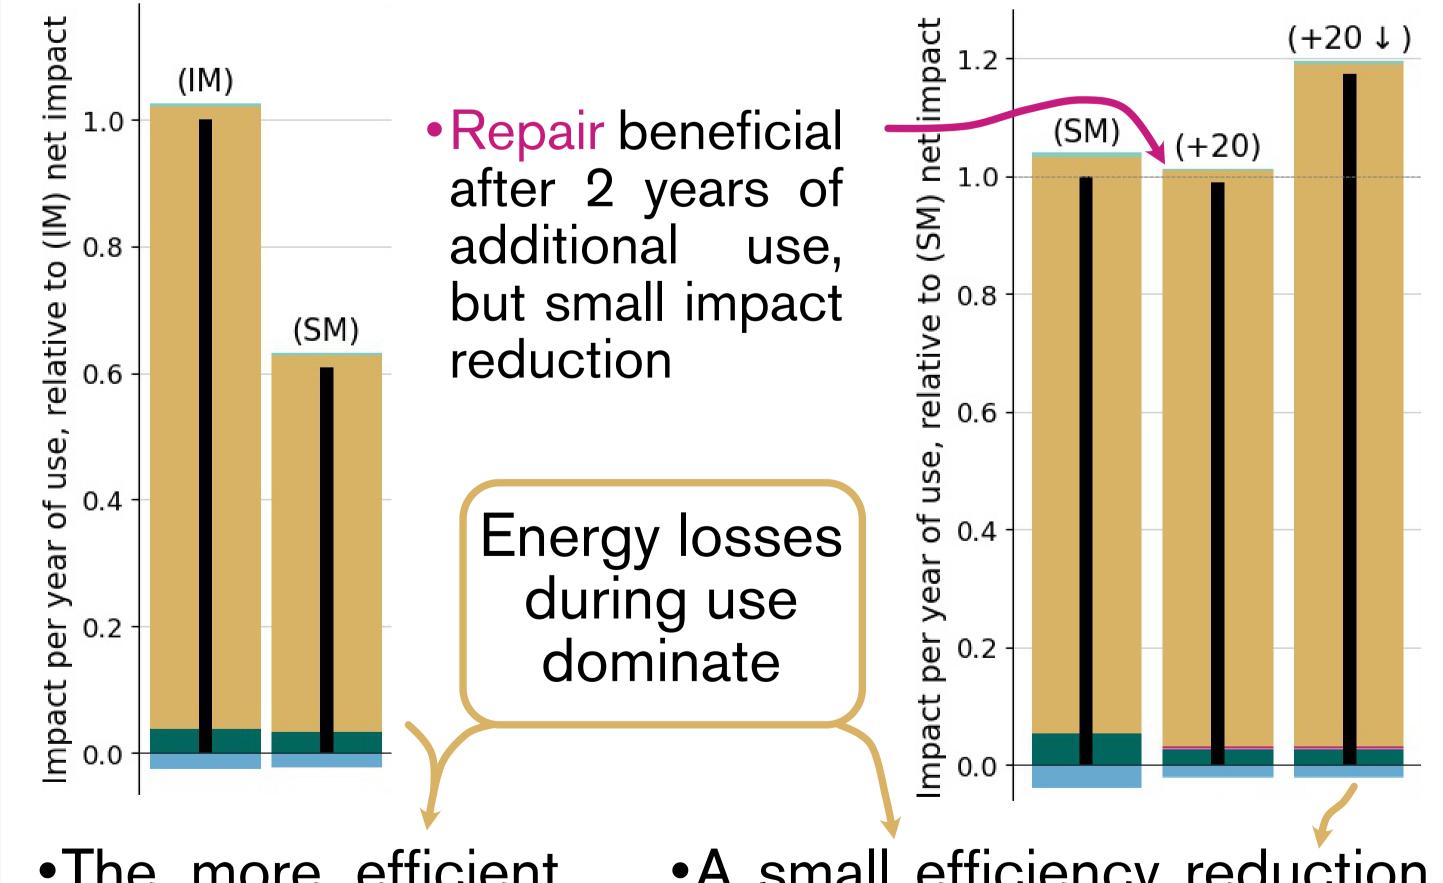

Legend

(IM): induction motor, used for 20 years (SM): synchronous motor, used for 20 years **Motor recycling Electricity losses during use Motor production Credits from motor recycling**

(+20): SM repaired and used for 20 additional years $(+20\downarrow)$: (+20) with an efficiency reduction of 0.6%

Rewinding

Old windings recycling Credits from windings recycling

(4) Sensitivity analysis

Changing the electricity mix:

- Baseline: mix of nuclear, hydro, bio and wind (Swedish mix)
- Low-carbon: hydroelectricity only
- High-carbon: oil-based only

Conclusions

After a minimum additional use only (2-7 years), repair is beneficial, but less than choosing a more energy-efficient design, and a small energy efficiency reduction outweighs the benefits of repair.

For LCAs of use extension of energy-using products: include resource use from electricity production and transmission.

•The more efficient SM results in lower impact than the IM.

•A small efficiency reduction (>0.05%) offsets the benefit of repair.

For motor manufacturers and users: focus on high energy efficiency rather than repairability.
